

If it ain't one type it's another

Tuples

1. Example for this lecture

Example: compute square root, or report that the input is negative

2. Returning two things

Simple solution:

```
// union/optroot.cpp
bool RootOrError(float &x) {
    if (x<0)
        return false;
    else
        x = std::sqrt(x);
    return true;
};

/* ... */
for ( auto x : {2.f,-2.f} )
    if (RootOrError(x))
        cout << "Root is " << x << '\n';
    else
        cout << "could not take root of " << x << '\n';
```

Other solution: tuples

3. Function returning tuple

How do you return two things of different types?

```
1  #include <tuple>
2  using std::make_tuple, std::tuple;
3
4  tuple<bool,float> maybe_root1(float x) {
5      if (x<0)
6          return make_tuple<bool,float>(false,-1);
7      else
8          return make_tuple<bool,float>(true,sqrt(x));
9  };
10
```

(not the best solution for the 'root' code)

4. Returning tuple with type deduction

Return type deduction:

```
1 // stl/tuple.cpp
2 auto maybe_root1(float x) {
3     if (x<0)
4         return make_tuple
5             <bool,float>(false,-1);
6     else
7         return make_tuple
8             <bool,float>
9             (true,sqrt(x));
10 };
```

Alternative:

```
1 // stl/tuple.cpp
2 tuple<bool,float>
3     maybe_root2(float x) {
4     if (x<0)
5         return {false,-1};
6     else
7         return {true,sqrt(x)};
8 };
```

Note: use *pair* for *tuple* of two.

5. Catching a returned tuple

The calling code is particularly elegant:

Code:

```
1 // stl/tuple.cpp
2 auto [succeed,y] = maybe_root2(x);
3 if (succeed)
4     cout << "Root of " << x
5         << " is " << y << '\n';
6 else
7     cout << "Sorry, " << x
8         << " is negative" << '\n';
```

Output:

```
Root of 2 is 1.41421
Sorry, -2 is negative
```

This is known as structured binding.

6. C++11 style tuples

```
#include <tuple>

std::tuple<int,double,char> id = \
    std::make_tuple<int,double,char>( 3, 5.12, 'f' );
// or:
std::make_tuple( 3, 5.12, 'f' );
double result = std::get<1>(id);
std::get<0>(id) += 1;

// also:
std::pair<int,char> ic = make_pair( 24, 'd' );
```

Annoyance: all that 'get'ting.

Optional

7. Optional results

The most elegant solution to ‘a number or an error’ is to have a single quantity that you can query whether it’s valid.

```
#include <optional>
using std::optional;
```

```
1 // union/optroot.cpp
2 optional<float> MaybeRoot(float x) {
3     if (x<0)
4         return {};
5     else
6         return std::sqrt(x);
7 };
```

8. Create optional

```
optional<float> f {  
    if (something)  
        // result if success  
        return 3.14;  
    else  
        // indicate failure  
        return {};  
}
```

9. Testing and getting value

Two ways:

```
// union/optroot.cpp
for ( auto x : {2.f,-2.f} )
    if ( auto root =
        MaybeRoot(x) ;
        root.has_value() )
        cout << "Root is " <<
            root.value() << '\n';
else
    cout << "could not take
        root of " << x << '\n';
```

```
// union/optroot.cpp
for ( auto x : {2.f,-2.f} )
    if ( auto root =
        MaybeRoot(x) ; root )
        cout << "Root is " <<
            *root << '\n';
    else
        cout << "could not take
            root of " << x << '\n';
```

Expected (C++23)

10. Expected

Expect double, return info string if not:

```
std::expected<double,string>
    square_root( double x ) {
    auto result = sqrt(x);
    if (x<0)
    return
        std::unexpected("negative");
    else if
        (x<limits<double>::min())
    return
        std::unexpected("underflow");
    else return result;
}
```

```
auto root = square_root(x);
if (x)
    cout << "Root=" <<
        root.value() << '\n';
else if (root.error()==/* et
        cetera */ )
    /* handle the problem */
```

Variants

11. Variant

- Tuple of value and bool: we really need only one
- variant: it *is* one or the other
- You can set it to either, test which one it is.

12. Variant methods

```
1 // union/intdoublestring.cpp
2 variant<int,double,string> union_ids;
```

Get the index of what the variant contains:

```
1 // union/intdoublestring.cpp
2 union_ids = 3.5;
3 switch ( union_ids.index() ) {
4 case 1 :
5     cout << "Double case: " << std::get<double>(union_ids) << '\n';
6 }
```

```
1 // union/intdoublestring.cpp
2 union_ids = "Hello world";
3 if ( auto union_int = get_if<int>(&union_ids) ; union_int )
4     cout << "Int: " << *union_int << '\n';
5 else if ( auto union_string = get_if<string>(&union_ids) ; union_string
6 )
7     cout << "String: " << *union_string << '\n';
```

(Takes pointer to variant, returns pointer to value)

Exercise 1

Write a function *first_factor* that optionally returns the smallest factor of a given input.

```
// primes/optfactor.cpp
auto factor = first_factor(number);
if (factor.has_value())
    cout << "Found factor: " << factor.value() << '\n';
else
    cout << "Prime number\n";
```

Exercise 2

Write a routine that computes the roots of the quadratic equation

$$ax^2 + bx + c = 0.$$

The routine should return two roots, or one root, or an indication that the equation has no solutions.

Code:

```
1 // union/quadratic.cpp
2 for ( auto coefficients :
3     { quadratic{.a=2.0, .b=1.5,
4         .c=2.5},
5       quadratic{.a=1.0, .b=4.0,
6         .c=4.0},
7       quadratic{.a=2.2, .b=5.1,
8         .c=2.5}
9     } ) {
10     auto result =
11         compute_roots(coefficients);
```

Output:

```
With a=2 b=1.5 c=2.5
No root
With a=2.2 b=5.1 c=2.5
Root1: -0.703978 root2:
        -1.6142
With a=1 b=4 c=4
Single root: -2
```
