Objects and classes

Victor Eijkhout, Susan Lindsey

Fall 2022
last formatted: March 27, 2023

Classes

1. Definition of object/class

An object is an entity that you can request to do certain things. These actions are the *methods*, and to make these possible the object probably stores data, the *members*.

When designing a class, first ask yourself: 'what functionality should the objects support'.

A class is a user-defined type; an object is an instance of that type.

2. Running example

We are going to build classes for points/lines/shapes in the plane.

```
1 class Point {
2    /* stuff */
3 };
4 int main () {
5   Point p; /* stuff */
6 }
```

Exercise 1

Thought exercise: what are some of the actions that a point object should be capable of?

3. Object functionality

Small illustration: point objects.

```
Code:
1 Point p(1.,2.); // make point (1,2)
2 cout << "distance to origin "
3      << p.distance_to_origin()
4      << '\n';
5 p.scaleby(2.);
6 cout << "distance to origin "
7      << p.distance_to_origin()
8      << '\n'
9      << "and angle " << p.angle()
10     << '\n';
```

```
Output:

distance to origin
    2.23607
distance to origin
    4.47214
and angle 1.10715
```

Note the 'dot' notation.

Exercise 2

Thought exercise:
What data does the object need to store to be able to calculate
angle and distance to the origin?
Is there more than one possibility?

4. The object workflow

- First define the class, with data and function members:

```
class MyObject {
  // define class members
  // define class methods
};
```

  (details later) typically before the `main`.

- You create specific objects with a declaration

```
MyObject
  object1( /* .. */ ),
  object2( /* .. */ );
```

- You let the objects do things:

```
object1.do_this();
x = object2.do_that( /* ... */ );
```

5. **Construct an object**

The declaration of an object x of class *Point*; the coordinates of the point are initially set to 1.5, 2.5.

Point x(1.5, 2.5);

```
1 class Point {
2 private: // data members
3   double x,y;
4 public: // function members
5   Point
6     ( double x_in,double y_in
      ) {
7       x = x_in; y = y_in;
8   };
9  /* ... */
10 };
```

Use the constructor to create an object of a class:
function with same name as the class.
(but no return type!)

6. Private and public

Best practice we will use:

```cpp
class MyClass {
private:
  // data members
public:
  // methods
}
```

- Data is private: not visible outside of the objects.
- Methods are public: can be used in the code that uses objects.
- You can have multiple private/public sections, in any order.

Methods

7. Class methods

Let's define method *distance*.

Definition in the class:

```
class Point {
  /* stuff */
  double distance_to_origin() {
    return sqrt(x*x + y*y); };
}
```
Use in the program:

```
Point pt(5,12);
double
  s = pt.distance_to_origin();
```

- Methods look like ordinary functions,
- except that they can use the data members of the class, for instance x, y;
- Methods can only be used on an object with the 'dot' notation. They are not independently defined.

Exercise 3

Add a method `angle` to the `Point` class. How many parameters does it need?

Hint: use the function `atan` or `atan2`.

You can base this off the file `pointclass.cxx` *in the repository*

Exercise 4

Make a class *GridPoint* which can have only integer coordinates.
Implement a function *manhattan_distance* which gives the distance
to the origin counting how many steps horizontal plus vertical it
takes to reach that point.

8. Food for thought: constructor vs data

The arguments of the constructor imply nothing about what data members are stored!

Example: create a point in x, y Cartesian coordinates, but store $r, theta$ polar coordinates:

```cpp
#include <cmath>
class Point {
private: // members
  double r,theta;
public: // methods
  Point( double x,double y ) {
    r = sqrt(x*x+y*y);
    theta = atan2(y/x);
  }
```

Note: no change to outward API.

Exercise 5

Discuss the pros and cons of this design:

```
1 class Point {
2 private:
3   double x,y,r,theta;
4 public:
5   Point(double xx,double yy) {
6     x = xx; y = yy;
7     r = // sqrt something
8     theta = // something trig
9   };
10  double angle() { return alpha; };
11 };
```

9. Data access in methods

You can access data members of other objects of the same type:

```
1 class Point {
2 private:
3   double x,y;
4 public:
5  void flip() {
6     Point flipped;
7     flipped.x = y; flipped.y = x;
8     // more
9   };
10 };
```

(Normally, data members should not be accessed directly from outside an object)

Exercise 6

Extend the Point class of the previous exercise with a method: distance that computes the distance between this point and another: if p,q are Point objects,

p.distance(q)

computes the distance between them.

Review quiz 1

T/F?

- A class is primarily determined by the data it stores.
  /poll "Class determined by its data" "T" "F"

- A class is primarily determined by its methods.
  /poll "Class determined by its methods" "T" "F"

- If you change the design of the class data, you need to change the constructor call.
  /poll "Change data, change constructor proto too" "T" "F"

10. Methods that alter the object

For instance, you may want to scale a vector by some amount:

```
  Code:
1 class Point {
2   /* ... */
3   void scaleby( double a ) {
4     x *= a; y *= a; };
5   /* ... */
6 };
7   /* ... */
8 Point p1(1.,2.);
9 cout << "p1 to origin "
10      << p1.length() << '\n';
11 p1.scaleby(2.);
12 cout << "p1 to origin "
13      << p1.length() << '\n';
```

```
Output:

p1 to origin 2.23607
p1 to origin 4.47214
```

Data initialization

11. Member default values

Class members can have default values, just like ordinary variables:

```
class Point {
private:
  float x=3., y=.14;
public:
  // et cetera
}
```

Each object will have its members initialized to these values.

12. Data initialization

The naive way:

```
1 class Point {
2 private:
3   double x,y;
4 public:
5   Point( double in_x,
6          double in_y ) {
7     x = in_x; y = in_y;
8   };
```

The preferred way:

```
1 class Point {
2 private:
3   double x,y;
4 public:
5   Point( double userx,
6          double usery )
7     : x(userx),y(usery) {
8   }
```

Interaction between objects

13. Methods that create a new object

Code:

```
 1 class Point {
 2   /* ... */
 3   Point scale( double a ) {
 4     auto scaledpoint =
 5         Point( x*a, y*a );
 6     return scaledpoint;
 7   };
 8   /* ... */
 9   cout << "p1 to origin "
10        << p1.dist_to_origin()
11        << '\n';
12   Point p2 = p1.scale(2.);
13   cout << "p2 to origin "
14        << p2.dist_to_origin()
15        << '\n';
```

Output:

```
p1 to origin 2.23607
p2 to origin 4.47214
```

Note the 'anonymous object' in the assignment

14. **Anonymous objects**

Create a point by scaling another point:

```
new_point = old_point.scale(2.81);
```

Two ways of handling the `return` statement:

Naive:

```
1 Point Point::scale( double a )
      {
2   Point scaledpoint =
3     Point( x*a, y*a );
4   return scaledpoint;
5 };
```

Creates point, copies it to `new_point`

Better:

```
1 Point Point::scale( double a )
      {
2   return Point( x*a, y*a );
3 };
```

Creates point, moves it directly to
`new_point`

'move semantics' and 'copy elision':
compiler is pretty good at avoiding copies

Optional exercise 7

Write a method *halfway* that, given two Point objects p,q, construct the Point halfway, that is, $(p+q)/2$:

```
Point p(1,2.2), q(3.4,5.6);
Point h = p.halfway(q);
```

You can write this function directly, or you could write functions Add and Scale and combine these.
(Later you will learn about operator overloading.)

How would you print out a *Point* to make sure you compute the halfway point correctly?

15. Using the default constructor

No constructor explicitly defined;

You recognize the default constructor in the main by the fact that an object is defined without any parameters.

Code:

```cpp
class IamOne {
private:
  int i=1;
public:
  void print() {
    cout << i << '\n';
  };
};
  /* ... */
  IamOne one;
  one.print();
```

Output:

```
1
```

16. Default constructor

Refer to point definition: 9
Consider this code that looks like variable declaration, but for objects:

```
Point p1(1.5, 2.3);
Point p2;
p2 = p1.scaleby(3.1);
```

Compiling gives (g++; different for intel):

```
pointdefault.cxx: In function 'int main()':
pointdefault.cxx:32:21: error: no matching function for call to
                'Point::Point()'
```

17. Default constructor

The problem is with *p2*:

```
Point p1(1.5, 2.3);
Point p2;
```

- *p1* is created with the constructor;
- *p2* uses the default constructor:

  ```
  Point() {};
  ```

- as soon as you define a constructor, the default constructor goes away;
- you need to redefine the default constructor:

  ```
  Point() {};
  Point( double x,double y )
    : x(x),y(y) {};
  ```

  (but only if you really need it.)

18. Other way

```
Point() = default;
Point( double x,double y )
  : x(x),y(y) {};
```

Also:

```
  Point() = delete;
```

to disable.

Exercise 8

Make a class LinearFunction with a constructor:

LinearFunction(Point input_p1,Point input_p2);

and a member function

```
float evaluate_at( float x );
```

which you can use as:

LinearFunction line(p1,p2);
```
cout << "Value at 4.0: " << line.evaluate_at(4.0) << endl;
```

19. Classes for abstract objects

Objects can model fairly abstract things:

Code:

```cpp
class Stream {
private:
  int last_result{0};
public:
  int next() {
    return last_result++; };
};

int main() {
  Stream ints;
  cout << "Next: "
       << ints.next() << '\n';
  cout << "Next: "
       << ints.next() << '\n';
  cout << "Next: "
       << ints.next() << '\n';
```

Output:

```
Next: 0
Next: 1
Next: 2
```

20. Preliminary to the following exercise

A prime number generator has:
an API of just one function: `nextprime`

To support this it needs to store:
an integer `last_prime_found`

Project Exercise 9

Write a class `primegenerator` that contains:

- Methods `number_of_primes_found` and `nextprime`;
- Also write a function `isprime` that does not need to be in the class.

Your main program should look as follows:

```
cin >> nprimes;
primegenerator sequence;
while (sequence.number_of_primes_found()<nprimes) {
  int number = sequence.nextprime();
  cout << "Number " << number << " is prime" << '\n';
}
```

Turn it in!

- If you have compiled your program, do:

  `coe_primes yourprogram.cc`

  where 'yourprogram.cc' stands for the name of your source file.

- Is it reporting that your program is correct? If so, do:

  `coe_primes -s yourprogram.cc`

  where the -s flag stands for 'submit'.

- If you don't manage to get your code working correctly, you can submit as incomplete with

  `coe_primes -i yourprogram.cc`

- If you don't understand what the script is telling you, try the debug flag:

  `coe_primes -d yourprogram.cc`

Project Exercise 10

The Goldbach conjecture says that every even number, from 4 on, is the sum of two primes $p + q$. Write a program to test this for the even numbers up to a bound that you read in. Use the `primegenerator` class you developed in exercise 35.

This is a great exercise for a top-down approach!

1. Make an outer loop over the even numbers e.
2. For each e, generate all primes p.
3. From $p + q = e$, it follows that $q = e - p$ is prime: test if that q is prime.

For each even number e then print e,p,q, for instance:

```
The number 10 is 3+7
```

If multiple possibilities exist, only print the first one you find.

Turn it in!

- If you have compiled your program, do:

  `coe_goldbach yourprogram.cc`

  where 'yourprogram.cc' stands for the name of your source file.

- Is it reporting that your program is correct? If so, do:

  `coe_goldbach -s yourprogram.cc`

  where the -s flag stands for 'submit'.

- If you don't manage to get your code working correctly, you can submit as incomplete with

  `coe_goldbach -i yourprogram.cc`

TACC

21. A Goldbach corollary

The Goldbach conjecture says that every even number $2n$ (starting at 4), is the sum of two primes $p + q$:

$$2n = p + q.$$

Equivalently, every number n is equidistant from two primes:

$$n = \frac{p + q}{2} \qquad \text{or} \qquad q - n = n - p.$$

In particular this holds for each prime number:

$$\forall_{r\,\text{prime}} \exists_{p,q\,\text{prime}} : r = (p + q)/2 \text{ is prime.}$$

Project Exercise 11

Write a program that tests this. You need at least one loop that tests all primes r; for each r you then need to find the primes p, q that are equidistant to it. Do you use two generators for this, or is one enough? Do you need three, for p, q, r?

For each r value, when the program finds the p, q values, print the p, q, r triple and move on to the next r.

Turn it in!

- If you have compiled your program, do:

  `coe_pqr yourprogram.cc`

  where 'yourprogram.cc' stands for the name of your source file.

- Is it reporting that your program is correct? If so, do:

  `coe_pqr -s yourprogram.cc`

  where the -s flag stands for 'submit'.

- If you don't manage to get your code working correctly, you can submit as incomplete with

  `coe_pqr -i yourprogram.cc`

Advanced stuff

22. Direct alteration of internals

Return a reference to a private member:

```
1 class Point {
2 private:
3   double x,y;
4 public:
5   double &x_component() { return x; };
6 };
7 int main() {
8   Point v;
9   v.x_component() = 3.1;
10 }
```

Only define this if you need to be able to alter the internal entity.

23. Reference to internals

Returning a reference saves you on copying.
Prevent unwanted changes by using a 'const reference'.

```
1 class Grid {
2 private:
3   vector<Point> thepoints;
4 public:
5   const vector<Point> &points() const {
6     return thepoints; };
7 };
8 int main() {
9   Grid grid;
10   cout << grid.points()[0];
11   // grid.points()[0] = whatever ILLEGAL
12 }
```

24. Access gone wrong

We make a class for points on the unit circle

```cpp
class UnitCirclePoint {
private:
  float x,y;
public:
  UnitCirclePoint(float x) {
    setx(x); };
  void setx(float newx) {
    x = newx; y = sqrt(1-x*x);
  };
};
```

You don't want to be able to change just one of x, y!
In general: enforce invariants on the members.

TACC

25. Const functions

A function can be marked as const:
it does not alter class data,
only changes are through return and parameters

26. 'this' pointer to the current object

Inside an object, a pointer to the object is available as `this`:

```
1 class Myclass {
2 private:
3   int myint;
4 public:
5   Myclass(int myint) {
6     this->myint = myint; // `this' redundant!
7   };
8 };
```

27. 'this' use

You don't often need the `this` pointer. Example: you need to call a function inside a method that needs the object as argument)

```
1 /* forward definition: */ class someclass;
2 void somefunction(const someclass &c) {
3   /* ... */ }
4 class someclass {
5 // method:
6 void somemethod() {
7   somefunction(*this);
8 };
```

(Rare use of dereference star)

Operator overloading

28. Operator overloading

Syntax:

```
<returntype> operator<op>( <argument> ) { <definition> }
```

For instance:

```
Code:
1 Point Point::operator*(double f) {
2     return Point(f*x,f*y);
3 };
4 /* ... */
5 cout << "p1 to origin "
6     << p1.dist_to_origin() <<
   '\n';
7 Point scale2r = p1*2.;
8 cout << "scaled right: "
9     << scale2r.dist_to_origin()
   << '\n';
10 // ILLEGAL Point scale2l = 2.*p1;
```

```
Output:
p1 to origin 2.23607
scaled right: 4.47214
```

Can also:

```
Point::operator*=(double factor);
```

Exercise 12

Revisit exercise 7 and replace the `add` and `scale` functions by overloaded operators.

Hint: for the `add` function you may need '`this`'.

29. Constructors and contained classes

Finally, if a class contains objects of another class,

```
1 class Inner {
2 public:
3   Inner(int i) { /* ... */ }
4 };
5 class Outer {
6 private:
7   Inner contained;
8 public:
9 };
```

30. When are contained objects created?

```
Outer( int n ) {
  contained = Inner(n);
};
```

1. This first calls the default constructor
2. then calls the `Inner(n)` constructor,
3. then copies the result over the `contained` member.

```
Outer( int n )
  : contained(Inner(n)) {
    /* ... */
};
```

1. This creates the `Inner(n)` object,
2. placed it in the `contained` member,
3. does the rest of the constructor, if any.

31. Copy constructor

- Default defined copy and 'copy assignment' constructors:

  some_object x(*data*);
  some_object y = x;
  some_object z(x);

- They copy an object:
  - simple data, including pointers
  - included objects recursively.

- You can redefine them as needed.

```
1 class has_int {
2 private:
3   int mine{1};
4 public:
5   has_int(int v) {
6     cout << "set: " << v
7          << '\n';
8     mine = v; };
9   has_int( has_int &h ) {
10    auto v = h.mine;
11    cout << "copy: " << v
12         << '\n';
13    mine = v; };
14   void printme() {
15    cout << "I have: " << mine
16         << '\n'; };
17 };
```

32. Copy constructor in action

```
Code:

1 has_int an_int(5);
2 has_int other_int(an_int);
3 an_int.printme();
4 other_int.printme();
5 has_int yet_other = other_int;
6 yet_other.printme();
```

```
Output:

set: 5
copy: 5
I have: 5
I have: 5
copy: 5
I have: 5
```

33. Copying is recursive

Class with a vector:

```
1 class has_vector {
2 private:
3   vector<int> myvector;
4 public:
5   has_vector(int v) { myvector.push_back(v); };
6   void set(int v) { myvector.at(0) = v; };
7   void printme() { cout
8       << "I have: " << myvector.at(0) << '\n'; };
9 };
```

Copying is recursive, so the copy has its own vector:

```
Code:

1 has_vector a_vector(5);
2 has_vector other_vector(a_vector);
3 a_vector.set(3);
4 a_vector.printme();
5 other_vector.printme();
```

```
Output:

I have: 3
I have: 5
```

34. Destructor

- Every class `myclass` has a *destructor* `~myclass` defined by default.
- The default destructor does nothing:

  `~myclass() {};`

- A destructor is called when the object goes out of scope. Great way to prevent memory leaks: dynamic data can be released in the destructor. Also: closing files.

35. Destructor example

Just for tracing, constructor and destructor do `cout`:

```
1 class SomeObject {
2 public:
3   SomeObject() {
4     cout << "calling the constructor"
5          << '\n';
6   };
7   ~SomeObject() {
8     cout << "calling the destructor"
9          << '\n';
10  };
11 };
```

36. Destructor example

Destructor called implicitly:

```
 Code:
1 cout << "Before the nested scope"
2     << '\n';
3 {
4   SomeObject obj;
5   cout << "Inside the nested scope"
6       << '\n';
7 }
8 cout << "After the nested scope"
9     << '\n';
```

```
Output:

Before the nested scope
calling the constructor
Inside the nested scope
calling the destructor
After the nested scope
```

Headers

37. C headers plusplus

You know how to use .h files in C.

Classes in C++ need some extra syntax.

38. Data members in proto

Data members, even private ones, need to be in the header file:

```
1 class something {
2 private:
3   int localvar;
4 public:
5   // declaration:
6   double somedo(vector);
7 };
```

Implementation file:

```
1 // definition
2 double something::somedo(vector v) {
3    .... something with v ....
4    .... something with localvar ....
5 };
```

39. Static class members

A static member acts as if it's shared between all objects.
(Note: C++17 syntax)

```
Code:
1 class myclass {
2 private:
3   static inline int count=0;
4 public:
5   myclass() { count++; };
6   int create_count() {
7     return count; };
8 };
9 /* ... */
10 myclass obj1,obj2;
11 cout << "I have defined "
12      << obj1.create_count()
13      << " objects" << '\n';
```

```
Output:

I have defined 2 objects
```

40. Static class members, C++11 syntax

```
1 class myclass {
2 private:
3   static int count;
4 public:
5   myclass() { count++; };
6   int create_count() { return count; };
7 };
8   /* ... */
9 // in main program
10 int myclass::count=0;
```
